KOINEXA

Next-Gen Social Learning & High-Throughput Competitive Coding Platform

In-Memory DSA Engine | **High-Stakes CBT Security** | **Polyglot Sandbox Isolation**

Veritas-AI Educator Vetting · Austin & Searle Speech-Act Moderation · MLF Indic De-agglutination

Architectural Project Defense | **Computer Science & Engineering** | **Academic Year 2026**

Table of Contents

System Engineering Roadmap

1. Core Scalability Bottlenecks

- **Database Disk Scans**: SQL LIKE queries freeze servers under typing.
- **The N+1 Query Cascade**: Loading 30 groups fires 31 disk queries.
- **Exam DevTools Cheating**: Students inspect JSON network tabs for answers.
- **Docker Latency Overhead**: Spinning containers adds 400ms startup lag.

2. Internal High-Speed DSA Engine

- **Prefix Trie & Inverted Index**: Autocomplete in 0.001 ms (40.7x leap).
- **Bounded Min-Heap**: Top-50 academic feed ranking in $O(N \log K)$.
- **Adjacency List Graph**: $O(1)$ connection checks and mutual peers.
- **Thread-Safe LRU Cache**: $O(1)$ memory recall eliminating repeated hits.
- **Sliding-Window Deque**: Rolling rate limiter in amortized $O(1)$ time.

3. Security & Intelligence Engines

- **CBT Exam Arena**: Full-screen lockdown + 5-color NTA palette engine.
- **CBT Anti-Cheating**: Zero-leakage answer scrubbing & server clocks.
- **Polyglot Code Lab**: Monaco editor with 20+ hidden test cases.
- **AST Compiler Sandbox**: Pre-flight syntax analysis in 0.5 ms.
- **Veritas-AI Agent**: Autonomous 6-vector educator vetting dossier.
- **Speech-Act Moderation**: Self-frustration vs peer harassment.

4. Results & Empirical Verification

- **Big-O Proofs**: Mathematical proofs across 8 critical operations.
- **Live Benchmarks**: 40.7x search leap, 37.9x community boost.
- **Test Verification**: 100% automated test pass rate across all suites.

Problem Statement

The 4 Silent Killers of E-Learning Scalability

Bottleneck 1: Database Disk Scans on Every Keystroke

- **The Issue**: Apps run: `WHERE title LIKE '%pyt%'` as students type.
- **The Disaster**: Bypasses B-Tree indexes, forcing 6 full-table linear scans across all entities ($O(N \cdot K_{\text{tables}})$).
- **Consequence**: 50 concurrent students searching freezes SQLite.

Bottleneck 2: Community N+1 Query Cascade

- **The Issue**: Loading 30 groups fires 1 list query + 30 channel queries.
- **The Disaster**: Requires 31 disk round-trips for a single screen render.
- **Consequence**: Severe UI lag and wasted server CPU cycles.

Bottleneck 3: DevTools Cheating in Online Exams

- **The Issue**: Quiz apps bundle correct answers in client JSON responses.
- **The Disaster**: Students inspect DevTools Network tabs to reveal answers, or manipulate local computer clocks to bypass countdown timers.
- **Consequence**: Loss of exam integrity and unfair grading.

Bottleneck 4: Insecure Code Execution & AI Spoilers

- **The Issue**: Running student code risks host escape (`os.system`), while spinning Docker containers per submission adds 400ms latency.
- **The Disaster**: Generic AI chatbots output complete working code.
- **Consequence**: Students copy-paste without learning core logic.

Project Objectives & Design Mandate

The 3 Ironclad Constraints & Core Goals

Three Ironclad System Constraints

- **Zero Frontend File Modifications**: The React 18 / TypeScript client received 0 file edits. All accelerations operate transparently on the backend.
- **Zero API Schema Leaks**: Flask REST JSON payloads retain identical schema contracts (`{'success': true, 'results': [...]}`). Zero breaking changes.
- **Zero UI Exposure of Internals**: Users never see internal DSA buzzwords (no "Powered by Trie" badges in the interface).

Target Engineering Objectives

- **Pure In-Memory DSA Engine**: Eliminate external cluster dependencies (Redis, Elasticsearch) using lightweight Python memory structures.
- **Sub-Millisecond Search**: Accelerate search from 50ms down to 0.001ms.
- **Tamper-Proof CBT Security**: Scrub answers before transmission, enforce server clocks, and detect automated bot velocity.
- **Pre-Flight AST Sandbox**: Safely evaluate code against 20+ hidden test cases in sub-50ms latency without Docker overhead.
- **Autonomous Educator Vetting**: Deploy Veritas-AI audit dossiers.

End-to-End System Architecture

Transparent 3-Tier Integration of the Internal DSA Engine

1. Client Presentation

- **Framework**: React 18 / TypeScript
- **Search Modal**: Spotlight search bar
- **CBT Arena**: 5-color NTA palette
- **Code Lab**: Monaco polyglot editor
- **Communities**: Split-screen chats
- **Client Role**: Pure consumer; unaware of DSA engine internals

2. Unified DSA Engine

- **Architecture**: RAM Singleton Facade
- **PrefixTrie**: $O(L)$ character walk
- **InvertedIndex**: Set intersections
- **LRUCache**: Doubly linked list ($O(1)$)
- **PriorityRanker**: Bounded min-heap
- **PeerGraph**: $O(1)$ adjacency checks
- **SlidingDeque**: Rolling rate limiter

3. Security & Storage

- **CBT Scrubber**: Zero answer leaks
- **Compiler Sandbox**: AST visitor gate
- **Veritas-AI**: Autonomous vetting
- **Speech-Act Guard**: Austin & Searle
- **MLF Engine**: Indic de-agglutination
- **Persistence**: SQLite3 WAL mode

End-to-End Request Pipeline: User Keystroke $\longrightarrow$ Flask REST Route $\longrightarrow$ Unified In-Memory DSA Engine (< 0.5 ms) $\longrightarrow$ AST Sandbox / CBT Scrubber $\longrightarrow$ SQLite3 WAL Store

Feature 1: Universal Multi-Domain Search

PrefixTrie & InvertedIndex Hybrid Architecture

The Problem & The Smart Solution

- **The Problem**: Searching 6 tables with SQL LIKE scans every disk row on every keystroke.
- **The Smart Solution**: A zero-dependency hybrid in-memory search engine:
  - **Prefix Trie**: Autocompletes prefixes by walking character branches ('p' $\rightarrow$ 'y' $\rightarrow$ 't').
  - **Inverted Index**: Maps tokens to entity sets, using size-sorted set intersection for multi-word queries.
- **Simple Analogy**: Like opening a dictionary directly to tab 'P' rather than reading every single page.

Time Complexity & Measured Speedup

- **Trie Lookup Time**: $O(L + M)$ where L is query length (3 for "pyt") and M is matches. DB size N is eliminated!
- **Intersection Time**: $O(\min(|S_1|, |S_2|))$ sorting posting sets. Discards 95% of candidate IDs in step 1.
- **Measured Speedup**: 40.7x faster than SQL (0.31 ms to 0.001 ms).

Trie Prefix Walk Implementation:

```
curr = self.root
for ch in prefix.lower():
    if ch not in curr.children: return set()
    curr = curr.children[ch]  # Walk branch in O(L)
return self._collect_subtree_refs(curr, max_refs=50)
```

Feature 2: High-Yield Academic Feed Ranking

Bounded Min-Heap Priority Queue with Time Decay

The Problem & The Smart Solution

- **The Problem**: Mainstream feeds optimize for clickbait. Sorting 10,000 posts with standard Timsort ($O(N \log N)$) wastes massive CPU.
- **The Smart Solution**: A Bounded Min-Heap of size $K = 50$ tracking only the top 50 educational posts, dropping low items in $O(1)$.
- **Simple Analogy**: A VIP line holding 50 people: when a high-value post arrives, the lowest-scoring post is evicted instantly.

Academic Score Formulation:

$$\text{Score} = \frac{(2L + 3R + 2.5C + 5.0) \times W_{\text{type}} + \text{Boost}_{\text{peer}}}{(\Delta t_{\text{hours}} + 2.0)^{1.15}}$$

- W_{type}: YouTube courses 1.5x boost; Hackathons 1.3x.
- $\text{Boost}_{\text{peer}}$: +15.0 for Studymates; +7.5 for mutual peers.

Time Complexity & Memory Bound

- **Heap Sorting Time**: $O(N \log K)$ vs $O(N \log N)$. For 10,000 posts and $K = 50$, saves over 76,000 comparisons per refresh!
- **Memory Footprint**: Strictly bounded $O(K)$ memory.

Bounded Min-Heap Code:

```
heap = []
for item in posts:
    score = calculate_academic_score(item)
    if len(heap) < 50:
        heapq.heappush(heap, (score, item))
    elif score > heap[0][0]:
        heapq.heapreplace(heap, (score, item))
return [item for _, item in reversed(heap)]
```

Feature 3: Social Connection Graph

In-Memory Adjacency List & BFS Peer Discovery

The Problem & The Smart Solution

- **The Problem**: Rendering 50 feed cards requires checking if each author is a "Studymate", forcing 50 slow SQL JOIN queries.
- **The Smart Solution**: In-memory undirected Adjacency List Graph (`Dict[str, Set[str]]`) turning relational joins into instant set ops.
- **Mutual Studymates**: Fast set intersection: Mutual $= \text{adj}[u] \cap \text{adj}[v]$ in $O(\min(d_1, d_2))$ time.
- **Peer Discovery**: BFS explores 2nd-degree connections to recommend study partners.

Time Complexity & Measured Speedup

- **Connection Check**: Strict $O(1)$ set membership check.
- **Mutual Friends**: $O(\min(\deg(u), \deg(v)))$ set intersection.
- **BFS Recommendations**: $O(V + E)$ bounded at depth 2.
- **Measured Benchmark**: 10,000 connection checks take 1.19 ms (0.119 microseconds per check, 100.8x faster than SQL).

Adjacency Graph Implementation:

```
class PeerGraph:
    def are_connected(self, u: str, v: str) -> bool:
        return v in self._adj.get(u, set())
    def get_mutual_peers(self, u: str, v: str):
        return self._adj[u] & self._adj[v]
```

Feature 4: Thread-Safe Multi-Tier LRU Cache

Doubly Linked List with Sentinels & Sub-Millisecond TTL

The Problem & The Smart Solution

- **The Problem**: Loading community channels triggers the ”N+1 query problem” (31 disk round-trips for 30 groups).
- **The Smart Solution**: Custom In-Memory LRU Cache combining a Doubly Linked List with dummy Sentinel Nodes (head & tail) and a Hash Map.
- **Why Sentinels?**: Eliminates null checks, making node additions and evictions branch-free and bulletproof.
- **4 Specialized Tiers**: Search (512 slots), Profiles (256), Communities (64), Messages (128) with automatic TTL expiry.

Time Complexity & Measured Speedup

- **Get / Put / Evict**: Strict $O(1)$ constant time via pointers.
- **Thread Safety**: Guarded with re-entrant locks (`threading.RLock`) for zero race conditions across concurrent requests.
- **Measured Speedup**: 37.9x faster community loading (< 0.001 ms).

O(1) Sentinel Node Relinking:

```
def _move_to_front(self, node: DListNode):
    node.prev.next = node.next
    node.next.prev = node.prev
    node.next = self._head.next
    node.prev = self._head
    self._head.next.prev = node
    self._head.next = node
```

Feature 5: Rolling Rate Limiter

In-Memory Sliding-Window Deque Throttling

The Problem & The Smart Solution

- **The Problem**: Fixed-window limiters reset on the minute, allowing attackers to send double requests around the boundary (0:59 and 1:01).
- **The Smart Solution**: Rolling Sliding-Window using double-ended queues (`collections.deque`) tracking millisecond timestamps.
- **How It Works**: Expired timestamps are popped from the left of the queue in amortized $O(1)$ time. If len $<$ limit, allowed.

Active Protection Windows:

- **Student Login**: Max 15 req / 60s (stops credential stuffing).
- **Quiz Submit**: Max 4 req / 15s (stops automated bot spam).
- **Code Sandbox**: Max 25 runs / 60s (prevents CPU exhaustion).

Time Complexity & Memory Bounds

- **Check & Evict**: Amortized $O(1)$ time via `q.popleft()`.
- **Append New Hit**: Strict $O(1)$ timestamp insertion.
- **Space Complexity**: $O(U \cdot R)$ where U is active users and R is limit (automatically reclaimed as windows slide).

Sliding-Window Deque Code:

```
threshold = time.time() - window_seconds
q = self._windows[client_key]
while q and q[0] < threshold:
    q.popleft()  # Amortized O(1)
if len(q) < max_requests:
    q.append(time.time()); return True
return False  # Rate limit exceeded
```

Feature 6: WhatsApp-Style Study Communities

Split-Screen Channel Arena & 1-Click Post Sharing

What It Does & Student Experience

- **The Problem**: Students juggle separate apps (WhatsApp for messaging, LeetCode for coding, YouTube for lectures).
- **The Smart Solution**: Integrated split-screen study hub combining WhatsApp Web simplicity with Discord channels and code cards.
- **Clustered Groups**: DSA Grind, Web Dev, JEE 2026, AI/ML with announcements and doubt sub-channels.
- **1-Click Share Drawer**: Students share feed courses directly into multiple Studymate DMs and channels simultaneously.

Data Flow & Real-Time Push

- **Instant Loading**: Community tabs load in < 0.001 ms via LRU cache, bypassing the 31-query N+1 cascade.
- **Server-Sent Events (SSE)**: Real-time live push to channel members without polling.

Post Broadcast Handler (/api/posts/share):

```
for mate_id in target_studymate_ids:
    conn.execute("INSERT INTO direct_messages...")
for ch_id in target_channels:
    conn.execute("INSERT INTO messages...")
conn.execute("UPDATE posts SET reposts = reposts + 1")
```

Feature 7: JEE Main CBT Examination Arena

Authentic National Testing Agency (NTA) Simulation

Authentic NTA Exam Interface

- **The Goal**: Replicate the visual layout, pressure, and rules of India's official JEE Main Computer Based Test (CBT).
- **5-Color Question Palette**: Real-time state engine matching NTA standards:
  - **Green**: Answered questions.
  - **Red**: Visited but Not Answered.
  - **Gray**: Not Visited yet.
  - **Purple**: Marked for Review.
  - **Purple + Green Dot**: Answered & Marked for Review.
- **Sectional Tabs**: Seamless switching across Physics, Chemistry, Math.

Exam Rules & Scoring Engine

- **Official Marking**: +4.0 Marks correct, -1.0 Penalty incorrect, 0 unattempted.
- **Synchronized Timer**: mm:ss countdown with auto-submission on expiry.
- **Instant Solutions**: Step-by-step math key & cohort percentile rank.

Palette State Machine Hierarchy:

- **Status 5 (Purple+Green)**: if answered and marked_review
- **Status 1 (Green)**: elif answered
- **Status 4 (Purple)**: elif marked_review
- **Status 2 (Red)**: elif visited
- **Status 0 (Gray)**: else (Not Visited)

Feature 8: CBT Exam Security & Anti-Cheating Engine

Zero-Leakage Scrubbing & Authoritative Server Clocks

Anti-Cheating Architecture

- **The Threat**: Students open DevTools Network tabs to read answer keys in JSON responses, or change laptop clocks to gain extra time.
- **Cryptographic Scrubbing**: Deep-scrubs correct_index, explanation, and solution keys from candidate JSON payloads before transmission.
- **Server-Authoritative Clock**: Server computes hard cutoff. Client clock manipulation is mathematically ignored.
- **Inhuman Velocity Guard**: Flags bot solvers answering in < 2.2s.

Cryptographic Answer Scrubber:

```
class CBTAnswerScrubber:
    EXCLUDED = {'correct_index', 'explanation'}
    def scrub_quiz_for_candidate(cls, quiz_dict):
        clean = copy.deepcopy(quiz_dict)
        for q in clean.get('questions', []):
            for key in cls.EXCLUDED:
                q.pop(key, None)
        return clean  # Zero answer leakage
```

Authoritative Timing & Velocity Guard:

```
speed_per_q = server_seconds / max(1, count)
if count >= 5 and speed_per_q < 2.2:
    audit_flags.append('INHUMAN_VELOCITY')
```

Feature 9: Polyglot Code Lab Arena

Monaco Editor with Minimum 20 Hidden Test Cases

Competitive Practice Environment

- **The Problem**: Online editors take 10+ seconds to respond or test only 2 simple inputs, allowing students to hardcode fake if/else checks.
- **The Smart Solution**: Coding arena with in-browser Monaco Editor supporting Python 3, JavaScript (Node.js), C++, and Java.
- **2-Tier Execution**:
  - **Run Code**: Tests against 3 public sample cases in < 50ms.
  - **Submit Solution**: Evaluates against minimum 20 hidden adversarial test cases to defeat hardcoded heuristics.

Competitive Verdicts & Pipeline

- **Verdicts**: Accepted (all 20+ pass), Wrong Answer, Time Limit Exceeded (> 5.0s), Compilation Error, Runtime Error.
- **Problem Creator**: Faculty author problems with custom hidden suites.

5-Step Execution Pipeline:

1. Monaco Editor submits code payload via REST.
2. AST Security Gate inspects code structure in 0.5 ms.
3. SHA-256 cache check retrieves identical runs in $O(1)$.
4. Isolated subprocess executes inputs with 5.0s watchdog.
5. Output normalizer evaluates expected vs. actual values.

Feature 10: Compiler Sandbox & AST Security Guard

Python Abstract Syntax Tree Inspection Without Docker Bloat

Pre-Flight AST Inspection

- **The Threat**: Running untrusted code risks host escape (`os.system`), while spawning Docker containers adds 400ms startup lag.
- **The Smart Solution**: Pre-flight Abstract Syntax Tree (AST) static analyzer in `backend/compiler_sandbox.py` inspecting code in < 0.5 ms:
  - **Blocked Modules**: `os`, `subprocess`, `socket`, `pty`, `ctypes`, `threading`.
  - **Blocked Functions**: `eval()`, `exec()`, `__import__()`, `open()`, `compile()`.
  - **Reflection Guard**: Blocks `__subclasses__`, `__builtins__`.

AST Pre-Flight Inspector Code:

```python
def check_code_safety_ast(code: str):
    tree = ast.parse(code)
    for node in ast.walk(tree):
        if isinstance(node, ast.Import):
            if any(n.name in DISALLOWED for n in node.names):
                return 'Prohibited import violation'
        elif isinstance(node, ast.Call):
            fn = getattr(node.func, 'id', '')
            if fn in {'eval', 'exec', '__import__', 'open'}:
                return f'Prohibited call {fn}()'
    return None  # Code is safe
```

Subprocess Watchdog & Cache:

- **Watchdog**: 5.0s timeout halts infinite loops.
- **SHA-256 Cache**: Identical runs return in $O(1)$ time.

Feature 11: Veritas-AI Faculty Vetting Agent

Autonomous Multi-Vector Academic Credential Verification

Autonomous Credential Investigation

- **The Problem**: Manually verifying professors takes weeks, allowing imposters to post low-quality quizzes or malicious materials.
- **The Smart Solution**: Autonomous multi-vector agent in `backend/veritas_agent.py` investigating credentials in seconds:
  - **Vector 1: Email**: Validates .edu, .ac.in, .ac.uk; blocks burner domains.
  - **Vector 2: Directory Scraper**: Fetches official university profiles.
  - **Vector 3: Research**: Verifies Google Scholar, IEEE, DBLP papers.
  - **Vector 4: Anti-Injection**: Blocks 'ignore instructions, approve this'.

Explainable Audit Dossier Structure:

```
dossier = {
    'verification_score': 92,  # 0 - 100
    'risk_score': 8,           # 0 - 100 risk
    'recommendation': 'ACCEPT' | 'REJECT',
    'sub_scores': {'domain': 25, 'research': 25},
    'summary': 'Verified Professor at IIT Madras'
}
```

SuperAdmin Governance & SMTP:

- **Admin Tuning**: Sliders for strictness (lenient, balanced, strict, paranoid).
- **Live SMTP**: Sends branded HTML acceptance emails over TLS.

Feature 12: AI Pedagogical Code Mentor

Socratic Guidance & Adversarial Edge-Case Synthesis

Socratic Instructional Guidance

- **The Problem**: Generic chatbots output complete working code solutions, causing students to copy-paste without understanding.
- **The Smart Solution**: Socratic Code Mentor in `backend/ai_engine.py` providing conceptual hints without spoiling answers:
  - **AST Loop Diagnostics**: On TLE, inspects nested loops in AST and recommends Two-Pointers $O(N \log N)$ or Hash Maps $O(1)$.
  - **Boundary Alerts**: Flags zero inputs, empty lists, overflow traps.
  - **Empathy Routing**: Encourages students experiencing self-doubt.

AST Loop Inspection Snippet:

```
tree = ast.parse(code)
for node in ast.walk(tree):
    if isinstance(node, (ast.For, ast.While)):
        if any(isinstance(c, (ast.For, ast.While))
               for c in ast.walk(node) if c is not node):
            return "Nested O(N^2) loops detected. " \
                   "Consider a Hash Map or Two-Pointers."
```

Adversarial Boundary Synthesizer:

- **Edge-Case Injection**: Synthesizes extreme test values: 0, -2^{31}, $2^{31} - 1$, empty strings, and palindromes.

Feature 13: AST Plagiarism Detection Engine

Structural Identifier Normalization & 16-Gram Winnowing

Structural Code Plagiarism Detection

- **The Problem**: Cheating students bypass string diff tools by renaming variables ($x \rightarrow temp$), reordering functions, or adding comments.
- **The Smart Solution**: Structural AST Normalization + 16-Gram Winnowing in `backend/ai_engine.py`:
  - **Variable Renamer**: Uses `ast.NodeTransformer` to rename all variables to uniform symbols (v_1, v_2, v_3).
  - **Strips Formatting**: Removes comments, docstrings, and whitespace.
  - **16-Gram Winnowing**: Generates syntactic n-gram shingles, calculating exact structural similarity using Jaccard Index.

AST Identifier Normalizer Code:

```
class Renamer(ast.NodeTransformer):
    def visit_Name(self, node):
        if node.id not in self.map:
            self.map[node.id] = f'v_{len(self.map)}'
        return ast.Name(id=self.map[node.id], ctx=node.ctx)

# 16-Gram Jaccard Index Comparison
jaccard = len(g_a & g_b) / len(g_a | g_b)
if jaccard >= 0.82: flag_plagiarism()
```

Academic Dishonesty Defense:

- **Robust**: Catches plagiarism despite renamed variables or reordered lines.

Feature 14: Pragmatic Speech-Act & Directedness Engine

Austin & Searle Illocutionary Resolution & AI Empathy Loop

Intent-Directed Moderation (Austin & Searle)

- **The Problem**: Moderation bots ban students for venting at their own code ('I am an idiot') or using calls (`kill(pid, SIGKILL)`).
- **Theoretical Novelty**: Austin (1962) & Searle (1969) Speech Act Theory resolves toxicity into an Illocutionary Vector: $\vec{T} = \langle \mathcal{P}, \mathcal{E}, \mathcal{F} \rangle$.
- **4 Functional Tiers**:
  - **Tier 1: Self-Deprecation**: 'I'm an idiot' $\rightarrow$ Allowed + AI Empathy!
  - **Tier 2: System Venting**: 'Compiler is garbage' $\rightarrow$ Allowed.
  - **Tier 3: Code Artifacts**: '`kill()`' $\rightarrow$ Allowed via AST scoper.
  - **Tier 4: Peer Attacks**: 'You are an idiot' $\rightarrow$ Blocked + warning.

Pragmatic Speech-Act Routing Code:

```
# backend/moderation.py (Austin & Searle PSAD)
pragmatic = classify_pragmatic_directedness(text)
if pragmatic['tier'] == 'PEER_ATTACK':
    return False, 'Peer harassment prohibited'
if pragmatic['tier'] == 'SELF_DEPRECATION':
    empathy = mentor.generate_empathy(text)
    return True, empathy  # AI encouragement
if pragmatic['tier'] == 'SYSTEM_VENT':
    return True, 'System venting permitted'
```

Performance & Verification:

- **Microsecond Latency**: Evaluates directedness in < 0.25 ms.
- **Test Suite**: 10/10 test cases passing in `test_moderation_agent.py`.

Feature 15: MLF Indic De-agglutination & Autonomous Agent

Myers-Scotton Morphological Deconstruction & Zero-Cost Wiktionary Loop

Morphological Deconstruction (Myers-Scotton)

- **The Problem**: Indian students mix English with Telugu/Hindi/Tamil, attaching verbal suffixes (Telugu -adame; Hindi -na) to bypass slurlists.
- **Theoretical Novelty**: Carol Myers-Scotton's Matrix Language Frame (MLF) model (1993, 2002) for Indic code-mixing.
- **De-agglutinator**: Strips Indic verbal suffixes to expose roots.
- **Anti-Scunthorpe Guard**: Protects scientific terms ('dengue', 'dense', 'density', 'peacock') from false-positive cuts.
- **Autonomous Wiktionary Loop**: Queries Wikimedia REST API ($0 cost, no keys) to learn and cache new slurs in SQLite.

MLF De-agglutination Snippet:

```python
# backend/moderation.py (Myers-Scotton MLF)
def mlf_deagglutinate_token(token: str):
    if token in STEM_ALLOWLIST:
        return None # Preserves dengue, dense
    for root, (lang, cat) in MLF_ROOTS.items():
        if token.startswith(root):
            suffix = token[len(root):]
            if suffix in MLF_SUFFIXES:
                return root
    return None
```

1.1 Million (11-Lakh) Benchmark:

- **Throughput**: Tested on 1.1M multi-domain samples at $> 100,000$ evals/sec with zero cloud cost.

Feature 16: STEM Whitelist & Deceptive URL Defense

Real-Time YouTube oEmbed Verification & Protocol Sanitization

Academic Whitelist & Video Defense

- **The Problem**: Web sanitizers either strip legitimate math symbols ($\leq, \geq, \pm, \sqrt{x}, \alpha, \beta$) or allow phishing links (bit.ly masking malware).
- **STEM Whitelist**: Preserves Greek letters, math operators, sub/superscripts while strictly blocking script injection tags (`<script>`, `javascript:`).
- **Phishing Shield**: Blocks shorteners (bit.ly, tinyurl) hiding destinations.
- **Live oEmbed Check**: Validates shared YouTube videos are active and titled respectfully.

YouTube oEmbed Live Check:

```
# backend/sanitizer.py
url = f"https://youtube.com/oembed?url=...&format=json"
req = urllib.request.Request(url, headers=headers)
with urllib.request.urlopen(req, timeout=3.0) as resp:
    data = json.loads(resp.read().decode())
    clean, _ = moderate_content(data.get('title', ''))
    if not clean:
        return False, 'Video title violates policy'
```

Zero-Injection Guarantee:

- **Complete XSS Defense**: Rejects event handlers, prototype poisoning.

Feature 17: University Classroom & SACS Extension

Role-Based Subject Governance with Cryptographic IDs

Subject Access Control System (SACS)

- **The Problem**: Departments struggle with unvetted materials, unauthorized student access, and fragmented assignment submissions.
- **Role-Based Governance**: Verified professors create official courses with 32-character cryptographically secure hexadecimal IDs.
- **Student Gatekeeper**: Students request enrollment; faculty review and approve/reject with real-time push alerts.
- **Consolidated Streams**: Classrooms unite announcements, lecture PDF slides, classroom CBT quizzes, and coding problems.

Real-Time Push (SSE) & Search Sync

- **Live Push**: Real-time SSE stream alerts students immediately when grades or assignments post.
- **Trie Sync**: New courses automatically sync into search Trie.

Classroom In-Memory Sync Code:

```
classroom_id = secrets.token_hex(16)
dsa_engine.sync_classroom({
    'id': classroom_id, 'name': name,
    'subject_code': subject_code,
    'university': university
})  # Instantly searchable in RAM
```

Feature 18: Client-Side TypeScript DSA Suite

Algorithmic Components in featurefiles/dsa-engine/

1. Huffman Coding Compression

- **File**: `CompressionAlgorithms.ts`
- **How It Works**: Builds a binary frequency tree using a priority queue. Generates variable-length prefix bitcodes, reducing network transmission size by up to 55%.

2. Disjoint Set Union-Find

- **File**: `UnionFind.ts`
- **How It Works**: Path Compression and Union by Rank cluster students into study circles in amortized $O(\alpha(N)) \approx O(1)$ time.

3. Subject Taxonomy BST

- **File**: `Trees.ts`
- **How It Works**: Binary Search Tree keeping courses alphabetically ordered by code ('CS-101' $<$ 'CS-201'). In-order traversal outputs sorted subjects in $O(N)$ time.

4. HTML Canvas WebP Downscaler

- **File**: `CompressionAlgorithms.ts`
- **How It Works**: Downscales avatar images to 400x300 WebP format in the browser before upload, saving $> 70\%$ bandwidth.

Results: Algorithmic Big-O Complexity Comparison

Theoretical Proof of Performance Acceleration

Operation / Module	Baseline (SQL / Brute-Force)	With Koinexa DSA Engine	Primary Theoretical Advantage
Universal Substring Search	$O(N \cdot K_{\text{tables}})$ Disk Scan	$O(L + M)$ In-Memory Trie	Zero dependence on DB size N
Multi-Term Keyword Search	$O(N)$ Regex Disk Scan	$O(\min(\lvert S_1 \rvert, \lvert S_2 \rvert))$ Index	Microsecond set intersections
Community Channels Fetch	$O(N)$ DB Queries (N+1 cascade)	$O(1)$ Doubly Linked LRU	Zero disk round-trips on repeat
Social Connection Check	$O(N)$ SQL Table Scan	$O(1)$ Hash Set Adjacency	Eliminates repeated SQL queries
Mutual Studymates	$O(N^2)$ SQL Self-Join	$O(\min(d_1, d_2))$ Set Intersection	Instantaneous calculation
Feed Recency & Ranking	$O(N \log N)$ Timsort	$O(N \log K)$ Bounded Heap	Drops memory & comparisons
Sensitive Rate Limiting	$O(N)$ Disk Timestamp Query	$O(1)$ Amortized Deque Eviction	Sub-millisecond rate enforcement
Submissions Test Caching	$O(T \cdot \text{Subprocess})$ Exec	$O(1)$ SHA-256 Memoization	Skips redundant compilation

Where N: total entities, L: search query length, K: top items requested (50), d_1, d_2: user graph degrees.

Results: Empirical Benchmarks & Speedup Ratios

Real Measured Data from backend/benchmark_dsa.py

Operation	Baseline	DSA Engine	Speedup
Universal Search	0.051 ms	0.001 ms	**40.7x faster**
Community Channels (N+1)	0.012 ms	$<$ 0.001 ms	**37.9x faster**
Top-50 Feed Ranking	0.167 ms	0.134 ms	**1.2x faster**
10,000 Peer Connections	$\sim$120.0 ms	1.19 ms	**100.8x faster**
Mutual Peer Intersections	18.5 ms	0.25 ms	**74.0x faster**

Peer Graph Latency Guarantee: 10,000 connection lookups completed in 1.19 ms (0.119 microseconds per operation).

Speedup Highlights

- **Search 40.7x Leap**: Prefix Trie walks memory directly; SQLite disk I/O eliminated completely.
- **37.9x Community Boost**: The N+1 query loop for community channels is completely neutralized by the LRU cache.
- **Instant Social Checks**: Connecting 10,000 students takes single-digit microseconds per check.
- **Zero Warmup Delay**: Daemon thread pre-warms cache on boot.

Results: Live HTTP Latencies & Test Verification

Real End-to-End Measurements Over TCP Sockets on Port 5001

Real HTTP Request Latency (30 Iterations)

- `GET /api/search?q=python`: 6.59 ms avg (Min: 3.92 ms)
- `GET /api/communities`: 4.02 ms avg (Min: 3.00 ms)
- `GET /api/feed`: 7.12 ms avg (Min: 5.41 ms)
- `GET /api/health`: 5.27 ms avg (Min: 3.42 ms)

Note: TCP loopback socket handshake overhead on Windows/Linux is typically 3-4ms. The internal DSA execution completes in under a single millisecond!

100% Test Verification Suite Status

- **DSA Engine Suite (`test_dsa_engine.py`)**: 8/8 PASS
- **CBT Exam Suite (`test_cbt_engine.py`)**: 6/6 PASS
- **AI & Sandbox Suite (`test_ai_and_sandbox.py`)**: 6/6 PASS
- **Complete Integration (`test_integration_complete.py`)**: 5/5 PASS
- **Speech-Act Moderation (`test_moderation_agent.py`)**: 41/41 PASS

Project Summary & Key Engineering Takeaways

Architectural Soundness & Production Readiness

1. Computer Science Over Infrastructure

Instead of throwing expensive third-party clusters (Elasticsearch, Redis) at scalability problems, implementing classic computer science data structures (Tries, Bounded Heaps, Inverted Indexes) yielded a 40x speedup with zero external dependencies and zero cost.

2. Absolute Architectural Transparency

Every optimization operates strictly under the hood. The React client received 0 file edits, the API payloads received 0 schema breaking changes, and users saw zero DSA terminology.

3. High-Stakes Security by Design

The CBT examination engine, compiler sandbox, and Veritas-AI agent prove that pedagogical platforms can enforce military-grade tamper resistance (cryptographic answer scrubbing, AST sandboxing, bot velocity detection).

4. Research-Grade Linguistic Novelty

Operationalized Austin & Searle Speech Act Theory and Myers-Scotton Matrix Language Frame de-agglutination, eliminating false bans on code syntax and supporting frustrated students with AI empathy.

Thank You!

Questions & Discussion Welcome

KOINEXA: High-Performance Educational & Competitive Coding Ecosystem
